

- API will listen for POST requests to the `api/v1/register` endpoint and extract the provided email, phone, password, and confirm password from the request body.
- It will then validate that the password and confirm password fields match, and if they do, it will create a user object with the provided information and append it to the list of registered students.
- Then it will return a success message and a status code to indicate the user was successfully created.
- Can test API using cURL or Postman by sending a POST request.
